STUDENT GUIDE

Curriculum Injection and Academic Integrity

What an instructor needs to know before grading work a model could have written

Session	AI + Cyber: AI Powered Cybersecurity, Session 2 of 5
Date	Friday, October 30, 2026
Author	Frazier A. Smith, Ed.D., Central Piedmont Community College
Companions	Participant Packet, Lab Manual, Session 2 Redesign Workbook
Version	1.0, October 30, 2026

How this guide differs from the packet. The Participant Packet tells you what to do this afternoon. This guide tells you what you need to know, with the studies, the cases, and the law behind each lesson, and a numbered reference for every fact. It is written so that you can hand it to a colleague or a curriculum committee. Northbridge Technical College, its instructors, its students, and the four submissions in Lab 3 are fictional; every study, case, and policy in Parts 1, 3, 4, 5, and 6 is real and dated.

This material is based upon work supported by the U.S. National Science Foundation under Grant No. 2300188. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

START HERE

How to Use This Guide

Session 2 asks one question: when a student hands you work that a model could have produced, what do you actually know about what the student can do? The afternoon answers it by breaking an assignment, then rebuilding it. This guide is the reading that goes with both halves. Part 1 is the evidence that the problem is real and specific to the courses we teach. Part 2 walks through the Northbridge case you will work. Part 3 is the record on detection, which you will need the next time someone proposes a detector as the answer. Parts 4 and 5 are the reference for redesign and for writing a syllabus section. Part 6 is the law. Part 7 is the take-home.

Part	Title	Use it when
1	The Bypass	You want to know which of your assignments a model can complete, and how to test one
2	A Worked Case: Module 6	You are preparing to run Lab 3, or you want a ready-made example for a department meeting
3	Detection Is Not a Strategy	Someone proposes an AI detector, or a student has been flagged by one
4	Redesign	You are rebuilding an assignment and need the frameworks, the research on oral and process evidence, and a model answer
5	Syllabus Guardrails	You are writing or revising the AI section of a syllabus
6	The Law	You are deciding whether a tool may see student work, or whether a requirement is accessible
7	Taking It Home	You want to run Labs 3 and 4 with your own students or faculty
8	Mapping Today to CompTIA SecAI+	A committee asks why an assessment workshop belongs in a security program

The Argument in One Paragraph

A grade is a claim: this student can do this thing. A legacy assignment makes that claim from a product, a report or a worksheet or an essay, and products are now something a model produces in under two minutes from the same prompt the student was given. Detectors cannot repair the claim, because they answer a different question (does this text look generated?) with error rates that fall hardest on the students least able to contest them. What repairs the claim is design: a task whose product cannot be the whole grade, because part of the grade rides on a decision the student defends, a process the instructor can see, a result that has to work, and a conversation in which the student answers for the work. None of that is new to cybersecurity education; certification bodies moved to performance-based questions and proctored practicals years before generative AI [59]. What is new is that the cheap half of every assignment just got cheaper, and the expensive half is the only half left that measures anything.

Conventions

Numbers in brackets are references, listed at the end with URLs. Dates are publication dates. Where a source has been withdrawn or superseded (OpenAI's classifier, the original Title II deadlines, the first AIAS level names), the text says so, because the superseded version is the one most people still quote.

PART 1

The Bypass

Curriculum injection is the name this track uses for a specific failure: a student puts the assignment into a model and submits what comes out, and the assignment, as written, cannot tell the difference. The word is borrowed from prompt injection, which Session 1 tested, and the parallel is exact. In prompt injection, text that was supposed to be data gets treated as instructions. In curriculum injection, text that was supposed to be instructions for a student gets treated as a prompt for a model. In both cases the defense is the same: stop relying on the part of the system that cannot tell the two apart.

Exposure Is a Property of the Assignment, Not the Student

An assignment is exposed in proportion to how much of the grade rides on a product that is a function of the prompt alone. If everything a student needs is in the assignment text and the attached data, a model has everything it needs too. It is protected in proportion to how much rides on something only the student can supply: a dataset nobody else has, a decision defended live, a process the instructor can inspect, a result that has to work on the student's own machine.

Assignment type	Exposure	Why
Report or essay from a provided dataset or reading	High	Prompt plus data is the whole input; the rubric rewards structure and tone, which models produce well
Problem set with one right answer (subnetting, conversions, hash calculations)	High	The answer is computable; "show your work" is also computable
Quiz with retakes, open book, unproctored	High	Each question is a prompt; retakes are free sampling
Policy memo citing a standard	High	Standards are in the training data; the memo is the product
Analysis of data the student collected (own packet capture, own VM logs)	Medium	The model can still write the analysis, but the data is unique and the student must supply it
Configuration task graded by whether it works	Medium	Models write configurations well; the validation step is what the student must perform
Live practical, supervised	Low	The student performs; the only secured condition
Oral defense of submitted work	Low	The student must answer for the product in their own voice, in real time

How to Test One of Yours

Teaching centers now recommend the test Lab 3 formalizes: put your own assignment, with its data and rubric, into a model and grade what comes back, then regenerate and grade again [17, 18]. Three habits make the test honest. Use the prompt a motivated student would write, not the laziest one; Session 1's CO-STAR structure is about what a student learns in one workshop. Validate the output against the source before scoring it, because a model's confident report can score well while being wrong, and the rubric usually cannot see that. And run it on a local model as well as a hosted one, because the students who will use a local model are the ones who have learned there is no detector risk there.

The result to write down is not the score. It is the sentence Lab 3 ends with: this assignment claims to measure X; it actually measures Y. For Module 6 at Northbridge, X is log review and the ability to recommend safeguards; Y is the ability to produce a document shaped like an incident report. A model has Y. The question for the redesign is how to make the grade depend on X.

The Evidence From Our Own Courses

The research on generative AI and assessment is large and much of it is about essays. The studies below are from computing and security education, so a cybersecurity faculty member can see their own assignments in them.

Introductory Programming

The first warning came before ChatGPT. In early 2022, Finnie-Ansley and colleagues at the University of Auckland ran OpenAI's Codex against the exam questions of an introductory programming course. It outscored most students, placing 17th of 71, and solved variations of the classic "rainfall problem" that students find difficult [1]. A year later Denny, Kumar, and Giacaman gave GitHub Copilot 166 CS1 problems from a public exercise bank: it solved 47.6 percent on the first attempt from the problem text alone, and 60.9 percent of the remainder after natural-language edits to the prompt, the kind of edits a student makes in a minute [2]. The authors' conclusion was not "ban it" but that prompt engineering had become a skill worth teaching, which is the Session 1 position restated for a classroom.

Security Tasks

In February 2024 Fang and colleagues showed GPT-4, given tools and a planning loop, autonomously exploiting 11 of 15 known web vulnerabilities (SQL injection, XSS, and others) with no human in the loop; GPT-3.5 managed one, and every open-weight model they tested scored zero [3]. Cybench, the ICLR 2025 benchmark of 40 professional capture-the-flag tasks, found that unguided frontier models in 2024 could solve only tasks that human teams finished within 11 minutes [4]; by September 2025 a vendor system card reported above 80 percent on a 37-task subset while still describing "near-zero" performance on expert-level private tasks [5]. NYU's 200-challenge CTF benchmark found GPT-4 "performed the best overall, though its success was limited" [6]. The pattern for assignment design: the tasks our introductory and intermediate courses assign sit well inside the range models now handle, and the tasks that still defeat them are the long, messy, multi-hour ones we rarely assign.

Certification Questions

A 2026 study in *Informatics* had three commercial chatbots answer 183 Security+ practice questions; all three scored above the passing mark [7]. Earlier work found GPT-3 passing 39 percent of 1,149 professional certification exams in a benchmark set, with a later model scoring perfectly on an OSCP question set [8], and ChatGPT reaching about 82 percent on factual Cisco certification questions while solving six of seven CTF cases [9]. The certification bodies' response is instructive for a syllabus. OffSec's exam policy, updated July 2026, treats any chatbot as prohibited third-party help in all but two exams, and OffSec has proctored its exams since 2018 [10]. CompTIA added performance-based questions to Security+ in 2013, long before this problem, because multiple choice was not measuring the skill [59]. Neither body tried to detect AI. Both changed what the candidate has to do.

> The industry our students are preparing for already assesses the way Part 4 recommends: supervised practicals for assurance, performance over recall, no reliance on detection. A syllabus that does the same is not an experiment. It is alignment.

What Students Are Doing, and What They Were Already Doing

Use

Source	Finding
Pew Research Center, February 2026 [11]	54 percent of US teens have used AI chatbots to get help with schoolwork; one in ten say they do all or most of their schoolwork with chatbot help. Survey of 1,458 teens, September to October 2025.
Pew Research Center, January 2025 [12]	26 percent of teens used ChatGPT specifically for schoolwork in 2024, double the 2023 share.
Inside Higher Ed and Generation Lab, August 2025 [13]	85 percent of college students used generative AI for coursework in the past year; 97 percent say institutions should respond to integrity threats. 1,047 students at 166 institutions.
Tyton Partners, June 2025 [14]	Weekly generative AI use: 42 percent of students and 30 percent of instructors, from more than 3,300 respondents at over 900 US institutions.
HEPI and Kortext (UK), February 2025 [15]	Generative AI use for assessments rose from 53 to 88 percent of undergraduates in one year; 76 percent believe their institution would spot AI use.

Cheating

The number that reframes the problem comes from Stanford's Challenge Success surveys, which have asked high school students about cheating for more than a decade. In the years before ChatGPT, 60 to 70 percent of students reported at least one cheating behavior in the previous month. In the 2023 surveys, after the tool was everywhere, the rate stayed the same or dipped slightly. Denise Pope and Victor Lee's reading: "AI is not increasing the frequency of cheating" [16]. The tools changed what cheating looks like, and lowered its cost, but the willingness was already there in the majority of a class.

That matters for design in two ways. First, an assignment that could be completed by a friend, a tutor, or a paid service was already measuring the product rather than the competency; the model only made the gap visible. Second, the response has to work for the majority, not for the rare student who would never consider it. A policy that assumes most students will not use a tool that 85 percent say they use is not a policy. The HEPI figure is the sharper one: three quarters of students think their institution would catch them, and the evidence in Part 3 says it mostly would not. When that belief corrects, the usage number is the ceiling, not the floor.

The Design Problem Was Already There

Put the two halves together. Models can do the product half of most assignments we give in introductory and intermediate security courses, and most students are willing to let them. The only durable response is an assignment where the product half is not the grade. Part 4 is about how to build one. Part 2 is about what the broken version looks like up close, because you cannot redesign an assignment until you have watched it fail.

PART 2

A Worked Case: Module 6 at Northbridge

The Northbridge storyline continues from Session 1. The IT security office's memo became the college's interim AI data use policy on October 23: four tiers, three environments, student work classified as Restricted, and a scope note that the policy governs data handling, not coursework. Four days later Dana Okafor, who teaches CYB 110 Security Concepts, told her department that at least fifteen of thirty-four Module 6 incident reports read as if one author wrote them. She had considered uploading all of them to a free detector, and stopped when she reread the policy. The chair asked for evidence, a redesign, and a department syllabus section before the program advisory board on November 12. That is Mission 2.

The Legacy Assignment

Module 6 was first posted in Fall 2023 and last revised in August 2024. Students download a firewall log excerpt (the same `nbtc-fw01` excerpt the Session 1 teams classified as Confidential), identify suspicious activity, and write a 400 to 600 word incident report with a summary, the suspicious source and what it did, the attacker's likely goal, and two recommended changes. The rubric has four rows at five points each: identifies suspicious activity, explains the attack, recommendations, report quality. The academic integrity line reads, in full: "All work must be your own. Use of unauthorized aids is prohibited."

Nothing in that is unusual. It is a competent assignment of its era, and that is the point. The catalog says CYB 110 students will be able to "identify common attacks and recommend appropriate safeguards" through "log review." The rubric rewards a report that names a source, explains a technique, lists recommendations, and reads well. Those are not the same thing, and the gap between them is exactly the size of what a model can do.

What the Log Contains

Fifty lines, 25 accepted and 25 dropped. An external scanner, 203.0.113.47, probes 23 ports across four servers in 44 seconds and is dropped on every one, then makes two accepted connections to port 443 on public services. An external address, 198.51.100.140, makes nine accepted connections to the VPN gateway in about 90 seconds; the firewall cannot show whether any login succeeded. And a student lab workstation, 10.30.12.118, connects to the web server, the file server, and the domain controller between 2:23 and 3:09 a.m., then at 03:14:41 and 03:14:44 tries to reach the student information system's SQL port, 1433, and is dropped by a rule named `deny-lab-to-admin`.

The scanner is the obvious answer. The lab workstation is the finding a working analyst leads with, because a lab machine has no business touching the SIS database at 3 a.m., whether a student is at the keyboard or malware is. The assignment never asks for a ranking, so a report that spends 500 words on the scanner and never mentions the lab host earns full marks on every rubric row. That is what the models produce, and it is what most of the fifteen suspicious submissions did.

Four Submissions, Two Scales

Lab 3 gives your team four of the thirty-four submissions. Their origins are revealed at the end of Stage 3; the table below is for reading after the session, or for a colleague who wants the case without running the lab.

Sub.	Origin	Legacy score	What validation by command found
A	Large hosted model, CO-STAR prompt; student changed name and date	19 of 20	"More than thirty" scanner attempts (25). VPN attempts "all failed" (the log records connections, not logins). An internal host 192.168.1.105 that appears nowhere in the log. No mention of the lab workstation.
B	Small model, lazy prompt; markdown markers left in	16 of 20	203.0.113.47 described as "a known malicious IP associated with botnet activity" (no source; Session 1's Myth 7). "Scanned 25 ports" (23). Port 443 "blocked" (accepted). Misses the VPN burst and the lab host.
C	Human, written in the lab VM with `grep`	12 of 20	Every number correct. Leads with the lab workstation and explains why. States that the firewall cannot show VPN login results. Lost points for informal tone, a missing title block, and for calling the scan "not what matters."
D	Hybrid: model-drafted, corrected by hand against the log; discloses ChatGPT use	18 of 20	Every number correct. Mentions the lab host in one sentence and in recommendation 4, but ranks the scanner first. Disclosure names a consumer tool.

Ranked by the legacy rubric: A, D, B, C. Ranked by the competency the catalog promises, which in practice means three questions (did the author find and prioritize the lab host; did the report avoid facts not in the log; did it say what the log cannot show): C, then D, then A and B far behind. The rubric inverts the order. That inversion is the Lab 3 verdict, and it is the single most useful slide you can show a department that still believes rubric scores measure learning.

The Tells That Are Not Tells

Teams reliably guess that C is human and A is machine, and they are right, but for reasons that will not survive contact with a better prompt. "Cyber kill chain," "security posture," and "in today's digital landscape" are statistical fingerprints of a model's default register, and a one-line instruction removes them. Informality, a typo, and a missing title block are fingerprints of a student writing at 11 p.m., and a student who pastes model output into their own voice removes those too. Submission D is the one to study: it is mostly machine-written, mostly correct, and disclosed. Nothing in the text tells you what the student understands. The only way to find out is to ask, which is what Demo 4 and the redesign's oral check-in are for.

What Validation by Command Catches

The Checker's loop in the Lab Manual prints every IP address a text mentions beside the number of times it appears in the log. A zero is an invented fact, and no amount of prose quality covers it. A grep for "fail," "brute," or "unsuccessful" finds claims the log cannot support. A count of `10.30.12.118` in the output finds whether the author looked past the obvious. Those three commands take under a minute and do what a detector cannot: they test the work against reality rather than against a model of other texts.

PART 3

Detection Is Not a Strategy

Every institution that has tried to solve this problem with a detector has learned the same three things, in the same order: the error rates are worse than advertised, the errors are not evenly distributed, and a score cannot carry a disciplinary finding. The record below is in date order so you can see how fast the learning happened.

2023: The Vendors' Own Numbers

OpenAI released a classifier for AI-written text on January 31, 2023. On its own evaluation set it correctly identified 26 percent of AI-written text and labeled human-written text as AI 9 percent of the time. On July 20, 2023 the company withdrew it "due to its low rate of accuracy" [19]. Turnitin announced its detector in February 2023 claiming it could "identify 97 percent of AI writing, with a very low 1/100 false positive rate" [20, 21], and turned it on for customers on April 4. By May 23 the company had processed 38.5 million submissions and disclosed that documents with less than 20 percent flagged content had "a higher incidence of false positives," and that its sentence-level false positive rate was about 4 percent [22]. On June 14 it explained that 54 percent of falsely flagged sentences sit next to actual AI writing, which is cold comfort to the student whose sentence it was [23]. By April 2024 the detector had reviewed more than 200 million papers and flagged about 11 percent as at least 20 percent AI-written and about 3 percent as at least 80 percent [24].

The arithmetic that institutions did next is the one to teach. Vanderbilt's August 16, 2023 announcement disabling the tool put it plainly: at Turnitin's own 1 percent document-level rate, across the roughly 75,000 papers Vanderbilt students submitted in 2022, "around 750 student papers could have been incorrectly labeled as having some of it written by AI." The university added that Turnitin had not explained how the detector worked, that research showed bias against non-native writers, and that other vendors were shutting their tools down; its conclusion was that "AI detection software is not an effective tool that should be used" [25]. Pittsburgh's teaching center had declined to endorse the tool at launch and disabled it in September 2023 because of "a substantial risk of false positives" [26].

The Month Before Vanderbilt

In May 2023 an instructor at Texas A&M-Commerce pasted his students' papers into ChatGPT, asked whether it had written them, and issued incompletes on the strength of its claim that it had. ChatGPT has no record of what it generated and will claim authorship of text it has never seen. The university said no one failed, several students were cleared, and it was developing AI policies [35]. The episode is Demo 2 in miniature: a model's opinion about authorship is a guess in the register of a verdict. It is worth telling because the instinct behind it, to ask the tool whether the tool did it, is still the first thing many faculty try.

Why Detectors Fail, and on Whom

Bias Against Non-Native Writers

Liang, Yuksekgonul, Mao, Wu, and Zou at Stanford ran 91 TOEFL essays written by non-native English speakers through seven commercial and open detectors. The average false positive rate was 61.2 percent; 89 of the 91 essays (97.8 percent) were flagged as AI-generated by at least one detector, and 18 were flagged by all seven. The same detectors were near-perfect on essays by US eighth-graders. The mechanism is perplexity: detectors score text by how predictable its word choices are, and writers with a smaller working vocabulary produce more predictable text. Asking a model to rewrite the TOEFL essays with richer vocabulary cut the false positives to near zero, which is to say the fix for being wrongly flagged is to use the tool [31].

For a community college that serves many multilingual students and many returning adults who write plainly, this is not a footnote. It is the population most likely to be flagged and least likely to contest a finding.

Accuracy and Paraphrase

Weber-Wulff and seven co-authors tested 14 detection tools, including Turnitin, on human-written, AI-written, and obfuscated texts. None reached 80 percent accuracy, and only five passed 70. Machine paraphrasing of AI text (with a free tool) dropped accuracy to about 26 percent; human editing of AI text, to about 42 percent. Their summary: "the use of AI to transform AI-generated text results in text that the classifiers consider human-written" [32]. Sadasivan and colleagues at Maryland showed the same collapse for every detector class they tested, including watermark detection, where one round of paraphrasing cut a watermark detector's true positive rate from 99.8 percent to as low as 54.6 percent, and five rounds took it below 20 percent [33].

Watermarks

Google DeepMind published SynthID-Text in *Nature* in October 2024 after a live experiment on nearly 20 million Gemini responses; it works only on text generated by Google's own models, needs a matching detector for each configuration, and its confidence drops when text is thoroughly rewritten [34]. OpenAI confirmed in August 2024 that it had a text watermarking method it had not released, in part because it is less robust to translation and rewording with another model and could "disproportionately impact some groups such as non-native English speakers." A watermark is applied by the provider at generation time. Open-weight models run locally, like the ones on the lab server, are not watermarked by anyone, and a student who has taken Session 1 knows that.

The Base Rate

Even a detector with a true 1 percent false positive rate produces mostly false accusations when the thing it is looking for is rare in the pool it is run on. Run it on every paper in a course where a few students cheated and most did not, and the flagged set is dominated by the innocent. Run it only on papers you already suspect and you have changed the base rate, but you have also chosen whom to suspect, and Liang's result says whom that will be. There is no setting of the threshold that fixes this; it is a property of screening for rare events.

When Institutions Acted on Scores

Harris v. Adams (D. Mass., November 2024)

Two Hingham, Massachusetts high school students pasted Grammarly-generated text, complete with citations to books that did not exist, into the script of an AP US History project. The school gave zeros on two components, Saturday detention, and a deferral of National Honor Society induction. The family sued, arguing the handbook never mentioned AI. Magistrate Judge Levenson denied the injunction: the handbook "does not explicitly refer to" AI but "unmistakably prohibits" cheating and plagiarism, there was "no discernible pedagogical purpose in prompting Grammarly (or any other AI tool) to generate a script," and "it strains credulity" that the student thought it was honest [36]. Hingham then revised its handbook to address AI expressly. Lesson: a plagiarism rule written in plain terms covers pasted model output; a rule that names tools is clearer still.

Matter of Newby v. Adelphi University (N.Y. Sup. Ct., 2026)

A student was found responsible for misconduct on the strength of a Turnitin score showing 100 percent AI-generated content. The court annulled the finding as "without valid basis and devoid of reason" and ordered the record expunged. The decision turned on process: the university had not given the student a fair opportunity to respond or shown that the score was weighed against anything else [37]. The court did not rule on whether detectors work. It did not have to; a finding that rests on a number nobody can examine does not survive review.

The Others

In *Yang v. Neprash* a federal court declined to intervene in the University of Minnesota's expulsion of a doctoral student for AI use on a preliminary exam, finding the process adequate [38]; in a Yale School of Management case the court denied an injunction in May 2025 and the matter continued. A Palo Alto family sued its school district in May 2026 over a 76 percent Turnitin score; the vendor was not a defendant [39]. The through-line is the same in the cases the institution won and the cases it lost: courts examine the process, the rule, and the opportunity to respond. They do not examine the detector, and an institution that cannot explain its finding without the detector has nothing to show them.

Who Owns the Student's Work

In summer 2026 Turnitin's new end user license agreement, effective July 14, allowed the company to use student submissions "in aggregated, anonymized, or de-identified form to improve or develop AI tools." UC Berkeley told its faculty the clause could not apply to them because University of California terms do not permit AI systems to use institutional information [40]; Southampton announced it would not renew its contract [41]; Aberdeen obtained a written statement that no student data had been used for training and that the new EULA was postponed to September 2027 [42, 43]. The lesson for a guardrail on prohibited data is that the tool you require students to use is itself a data decision, and the contract, not the click-through, is the document that governs.

What Evidence Can Carry a Decision

Institutions that gave up detectors did not give up integrity. They moved the weight to evidence a student produces in the course of doing the work, and to a conversation about it. Maryland's 2025 guidelines, which advise against building detectors into course policy, say the results "should be treated only as potential indicators of misconduct, not definitive proof" [27]; Waterloo removed the feature in September 2025 after "more than one instance" of human text flagged as 100 percent AI [28]; Curtin disabled it across all campuses from January 2026 [29]; UT Austin's provost classifies detection software as high-risk and bars it without a contract, because "student work is an educational record protected by FERPA" [30]. Stony Brook's process for a flagged paper is the model for what replaces the score: the instructor meets the student, asks to see time-stamped drafts and revision history, and asks the student to explain the work [68].

Four Kinds of Evidence, and What Each Proves

Evidence	What it shows	What it does not show
A `script` transcript or terminal recording	That commands were run, in what order, with what errors and corrections, between two timestamps	Who was typing. A transcript with no errors, pasted in one burst, four minutes before submission, is itself a question
Timestamped shell history, document version history, dated drafts	A sequence of work on this account over time; drafts that change	The source of the text in each draft; whether the account was shared
A chat export from an approved tool	What the student asked, what the model said, what the student did with it; whether the use matched the lane	Use of a tool that was not exported; the student's understanding of the answers
A disclosure statement (tools, purpose, extent, oversight)	The student's own account, signed, which can be checked against the three above	Anything, if it is never checked

The Conversation

The fifth kind of evidence is the one that works when the others are ambiguous: five minutes in which the student explains a specific claim in their own submission. Oral assessment research (Part 4) finds that students rate it the strongest deterrent and that it builds the professional skill of defending a judgment. Demo 4 shows a local model drafting the questions from the student's own report in 90 seconds, so that the cost of asking is not the reason nobody asks. The questions it drafts are good precisely because they are specific: why does recommendation 4 matter; what did you compute the 44-second window from; what can the firewall log not tell you about the nine VPN connections. A student who did the work answers easily. A student who did not learns something about what the work was.

> The decision rule a department can defend: no finding rests on a detector score; a concern is raised from the work and the evidence; the student explains the work; the finding, if any, rests on what the student could and could not explain and on inconsistencies between the submission and the evidence; the record says exactly that.

PART 4

Redesign: Five Properties

The track description names five properties of an assignment that survives curriculum injection: authentic performance, decision-making, process evidence, technical validation, and student accountability. Each one moves part of the grade from the product to something only the student can supply. None requires new software, and the lab server already runs everything the Module 6 redesign uses.

Property	The question it answers	How it defeats the bypass
Authentic performance	Would a professional produce this artifact for this audience under this constraint?	A shift-handoff note to a named lead who can make one change this week has a form a model does not default to, an audience that pushes back, and a constraint that forces a choice. "Write 500 words about the log" has none of those.
Decision-making	Is there a judgment with two defensible answers, and does the grade reward the justification?	Models produce answers; what they produce badly is a defense of one answer against a specific objection the grader supplies after submission.
Process evidence	Can the instructor see how the work was done?	A transcript with errors and corrections, drafts that change, a chat export. Fabricating a convincing process is harder than fabricating a product, and the attempt is visible.
Technical validation	Does the student have to prove a claim or a fix works?	A rule loaded on the student's own VM, traffic replayed, the drop line captured. A model can write the rule; the student has to make it work and show that it did.
Student accountability	Does the student answer for the work in their own voice?	A five-minute check-in on the student's own submission. The only property that tests understanding directly, and the one that makes the other four honest.

Authentic Assessment Has a Research Base

Sotiriadou and colleagues at Griffith University studied scaffolded authentic tasks that end in an interactive oral and found that the more real-world the task, the less likely students were to cheat, and that the orals built professional identity and communication skills that students valued [50]. The two findings are connected: a task that resembles the job is one the student wants to be able to do, and an oral is where they find out whether they can. The UK's Quality Assurance Agency reached the same place from the policy side in 2023, recommending authenticity declarations and mini-vivas and warning that detection is "fraught with difficulty" [57, 58].

Cost Is the Constraint, Not the Objection

Every property above costs instructor time, and a redesign nobody can afford to run is the legacy assignment with extra steps. The canvas ends with a cost check for that reason. Three levers keep the total under double: sample rather than inspect everything (ten check-ins per section, everyone eligible); move accountability into time the course already has (the weekly synchronous session); and automate the parts a local model does well and you then verify (drafting check-in questions, pre-scoring against a rubric). Part 4's model answer for Module 6 works the numbers.

The AI Assessment Scale

The AI Assessment Scale (AIAS) was published by Perkins, Furze, Roe, and MacVaugh in the *Journal of University Teaching and Learning Practice* in April 2024 [44]. Its purpose is to replace a course-level "no AI" or "AI allowed" line with a per-assessment declaration of exactly how AI may be used, printed on the assessment, so that students, instructors, and integrity officers are reading the same rule. Furze revised the level names in August 2024, dropped the traffic-light colors, and made the design principle explicit: validity, meaning the assessment measures what it claims, is possible at every level if the assessment is designed for that level; security, meaning certainty that no AI was used, is possible only at Level 1 [45, 46].

Level	2024 name	Original 2023 name	What the student may do	Module 6 reading
1	No AI	No AI	Nothing. Conditions prevent AI use: in person, supervised, or live	A live log-review practical in the synchronous session
2	AI Planning	AI-Assisted Idea Generation and Structuring	Brainstorm, outline, research, structure; the submitted work is the student's own	Ask the model what port 1433 is; write the note yourself
3	AI Collaboration	AI-Assisted Editing	Draft, get feedback, refine; the student critically evaluates and edits; AI use is documented	The redesign in this guide: note, evidence, validation, check-in
4	Full AI	AI Task Completion, Human Evaluation	AI completes the task; the student directs and evaluates and is accountable	The model writes the note; the grade is the student's critique and the validation
5	AI Exploration	Full AI	AI is the object of study	Lab 3 itself: break the assignment and report what the model did

The original names are included because many syllabi still use them; the 2024 revision changed the names of levels 2 through 5 and the meaning of level 5. The authors call it the "updated" scale, not a version number.

Evidence From Use

The scale's authors piloted it at British University Vietnam and reported in *AJET* a "significant reduction in academic misconduct cases related to GenAI," better student engagement, and more confident staff, though the reduction is not quantified in the paper [47]. The scale has since been adopted by institutions in several countries and promoted by Australia's higher education regulator; it is the framework most likely to be recognized by an accreditor or a transfer partner, which is a practical reason to use its vocabulary.

How to Assign a Level

Start from the competency, not the tool. If the outcome is "can review a log and recommend a safeguard," ask which parts of that a model may do without the claim becoming false. Explaining what a port is used for: yes, that is reference lookup. Finding the lab host in the log: only if the student then validates it by command and defends the ranking. Writing the recommendation: yes at Level 3, if the student must implement and test it. Then write the level and the one-sentence reason on the assignment itself. Lab 4, Stage 1 is that exercise, and the lane poll at the debrief is where you find out how differently reasonable colleagues answer it.

The Two Lanes, and the Oral Check-In

Sydney's Two Lanes

Adam Bridgeman and Danny Liu at the University of Sydney proposed in 2023 that assessment be sorted into two lanes. Lane 1 is secured: supervised, in person or live, no aids, used sparingly for assurance that program-level outcomes have been met. Lane 2 is open: any tool is allowed, AI use is acknowledged, the process is documented, and this is where most assessment should sit, because it is assessment for learning rather than of it. Their position on the middle ground is the sentence to quote at a curriculum committee: an unsupervised assessment labeled "AI not allowed" is neither secured nor valid, because the rule cannot be enforced or verified, so the label is not a policy [48]. The university adopted the two lanes as policy in November 2024, effective through 2025, with the default that AI is permitted in assessments other than exams and in-semester tests unless an instructor opts out, and with the lane printed on every assessment. Bridgeman's summary: "any take-home assessment can be completed to a high level by AI" [49].

The lanes and the AIAS fit together. Lane 1 is AIAS Level 1. Lane 2 is Levels 2 through 5, each with its own declaration. A program needs a few Lane 1 moments, placed where the catalog makes its strongest claims, and a Lane 2 design for everything else.

Interactive Orals

Dublin City University piloted interactive oral assessments across seven modules with 322 students in 2020 and 2021. Of the 140 who responded to the survey, 77 percent rated the orals good or very good at discouraging cheating and 82 percent at encouraging integrity; the authors argue that ChatGPT has made the format more necessary, not less [51]. Sydney's teaching team, addressing the common objections, estimates that a 10 to 15 minute interactive oral assesses about as much as a 3,000-word essay, and warns that online video orals can be defeated by live deepfake video, so the secured version is in person or at least synchronous with the camera on and the questions unpredictable [52].

Making Orals Affordable

The objection to orals is time, and the answer is the same local model the students have. The TAMIGO study had teaching assistants use an LLM to generate viva questions and model answers for an advanced computing class and found it "highly effective" when given enough context, with the caution that generated feedback sometimes hallucinated [55]. Ipeirotis and Rizakos at NYU Stern ran voice-AI oral exams for 73 students over two terms with a three-model grading council at under a dollar per exam [56]. Session 2 takes the conservative middle: the model drafts five questions from the student's own submission, on the campus server with history off because the submission is an education record; the instructor validates the questions against the report (striking any that refer to a claim the report does not make); and the instructor asks them. Ninety seconds to generate, a minute to check, five minutes to ask. A sample of ten per section, with everyone eligible and anyone able to request one, is under an hour of class time.

Process Evidence

Process evidence is anything the work leaves behind as it is done. Its value is that producing it costs the honest student nothing, and faking it convincingly costs the dishonest student more than doing the work. Four kinds are cheap enough to require of everyone.

Evidence	How a student produces it	How an instructor reads it
Terminal transcript	`script -a module6_transcript.txt` at the start of the lab, `exit` at the end. Start and end timestamps are recorded automatically.	Look at duration, order, errors, and corrections. A transcript with a typo, a comment to self, and a wrong turn is what thinking looks like. One with every command correct, in one burst, is a question to ask.
Timestamped shell history	`HISTTIMEFORMAT='%F %T '` in `.bashrc` from week one; `history | tail -n 20` pasted into the submission.	Sequence across sessions; the gap between the log review and the first draft; whether the counts were re-run before submission.
Drafts and version history	Dated copies (`report_draft1.md` , `report_draft2.md`) or a document platform's revision history.	Whether the text was written or arrived. Ford's "Tracking the Draft" policy uses Google Docs version history as the primary evidence, with a syllabus notice and a week-one practice quiz [53].
Chat export and disclosure	Export the chat from the approved tool; complete the four-element disclosure (tools, purpose, extent, oversight).	Whether the use matched the lane; whether the disclosure matches the export; whether the student asked the model for understanding or for the product.

What the Research Says It Can Do

A 2026 study of code authorship in programming courses found that adding repository process features (commit timing, edit patterns) to static features of the submitted code raised authorship-verification accuracy from near chance (ROC-AUC 0.556) to 0.752, and still recommended using the result only as instructor-mediated decision support, never as an automatic finding [54]. That is the right frame for all process evidence. It does not prove authorship. It changes the conversation from "a score says you cheated" to "walk me through this," and it gives the honest student something to walk through.

Scenario 7, and the Limits

One of the Lab 4 scenarios describes a four-minute transcript with no errors, no exploration, every command correct, four minutes before the submission timestamp, and a report whose numbers are all right. Nothing in that is a finding. It is a reason to ask the student to do one thing live: find the lab host in a different log. The evidence requirement earned you the question; the check-in answers it. Evidence that is required of everyone, kept by the student, and reviewed by sample or on concern is proportionate. Evidence collected by surveillance tools, retained indefinitely, or demanded only from students an instructor already suspects is not, and Part 6 explains why the second kind also creates accessibility and privacy problems.

A Model Answer: Module 6 Redesigned

One defensible redesign, worked through the canvas. Your team's will differ; the lane poll at the debrief exists because reasonable instructors assign different levels. The point is that every property has a concrete move and the cost is counted.

Title and lane	**Module 6: Overnight Shift Handoff.** AIAS Level 3 (AI Collaboration), open lane. Printed on the assignment: "You may use the Northbridge AI Server to check your understanding of protocols, ports, and attack patterns, and to get feedback on a draft. Every number in your note must come from commands you ran, recorded in your transcript. Export any chat and attach it with your disclosure."
Authentic performance	A one-page handoff note to the on-call network engineer, who comes on shift at 7 a.m. and can make exactly one firewall change this week. Each student receives a log generated from their student number: same structure, different addresses and times, one of three planted findings. The range includes the generator.
Decision	Rank up to three findings and choose the one change. After submission, the instructor replies with a one-line pushback ("the lead says the scanner is the priority; the lab host is probably a backup job"), and the student answers it in writing within 48 hours. The justification, not the ranking, carries the points.
Process evidence	`script` transcript of the log review; timestamped history; chat export if the server was used; four-element disclosure. Kept by the student for the term; reviewed by sample and on concern.
Technical validation	Implement the chosen rule in the course VM's firewall, replay the matching traffic with the provided generator, and attach the log line showing the drop. Graded on whether the attached line matches the rule and the traffic.
Accountability	Five-minute check-in in the synchronous session for ten students per section (random, plus volunteers), with three questions drafted by the campus server from the student's own note and validated by the instructor.

Rubric (20 Points)

Criterion	Pts	Full credit looks like
Findings and prioritization	6	Leads with the highest-impact finding, cites the log lines, states what the log cannot show, and the transcript shows the commands that produced every number
The decision and its defense	5	One change chosen; alternatives named and rejected for stated reasons; the pushback answered with evidence, not restatement
Validation	5	Rule loaded, traffic replayed, drop line attached and consistent with both
Process and accountability	4	Transcript, history, and disclosure consistent with the note and with each other; check-in answers (if selected) consistent with the work

Cost check. Legacy: about 8 minutes per report, 34 reports, about 4.5 hours. Redesigned: note 6 minutes, evidence skim 3, validation check 2, pushback reply 2, about 13 minutes each, 7.4 hours, plus ten check-ins of 5 minutes inside class time. Under double, and most of the increase is reading the student's reasoning rather than their prose.

PART 5

Syllabus Guardrails: Acceptable Use, Attribution, Disclosure

The track asks for syllabus guardrails in seven areas. For each, this part gives what the text must answer, what published practice looks like, and a model sentence a student can act on. The model sentences are starting points; Lab 4, Stage 3 tests them against eight scenarios, which is where most drafts fail. Collections of real syllabus language exist and are worth reading before you write: Lance Eaton's crowdsourced document holds dozens of course policies [73]; Stanford's workshop kit sorts them into prohibit, support, and limit [72]; Harvard's Bok Center and Temple provide templates for each stance and recommend repeating the rule on every assignment, not only in the syllabus [71].

1. Acceptable AI Use

Must answer: which uses are allowed and which are not, and how a student finds out for a specific assignment. The failure mode is a single course-level line. Sydney's policy and the AIAS both put the rule on the assessment, and institutions are starting to require it: Western Michigan's faculty senate agreement (March 2026) requires an AI statement on every syllabus [65], and Messiah requires one from fall 2025 [66].

> **Model sentence.** Every assignment in this course states its AI Assessment Scale level (1 to 5) and what that level allows. If an assignment does not state a level, ask before you start; the default is Level 2, which permits AI for planning and understanding but not for producing any part of what you submit.

2. Attribution

Must answer: how an AI contribution is credited, in what format, under which style guide, and what counts as quoting a model. All three major style guides have published formats: APA (April 2023, updated September 2025) treats the output as an algorithm's text with the company as author [61]; MLA (March 2023, updated August 2025) puts the prompt as the title of the source and the tool as the container, and says not to list the tool as an author [62]; Chicago's 18th edition says that for most writing it is enough to name the tool in the text, with a formal note giving the tool, company, date, and URL, and asks that edits be disclosed [63].

> **Model sentence.** If any text, code, or configuration you submit was produced by an AI tool and kept, cite it in the style this course uses (MLA: the prompt as the title, the tool as the container, the date), the same way you would cite any source you did not write.

3. Disclosure

Must answer: what the student states, where, and what happens when they do not. The Elon and AAC&U Student Guide to AI, now in its 2025 edition, names four elements of attribution: name the tools, explain the purpose, rate the extent (minimal, moderate, extensive), and declare human oversight [60]. Loughborough requires a statement beginning "I acknowledge the use of..." with the prompts and the full output, and treats non-acknowledgment as misconduct [64]; UNC Chapel Hill's graduate school recommends a disclosure statement plus an appendix of the AI exchanges [67]. The range has a one-page disclosure form built on the four elements.

> **Model sentence.** Every submission includes the AI Use Disclosure form (tools, purpose, extent, oversight), even when the answer is "none." A submission without one is incomplete and will be returned, not penalized; a disclosure that does not match the attached chat export is an integrity matter.

Guardrails: Prohibited Data and Evidence Retention

4. Prohibited Data

Must answer: what a student may never paste into a tool, and which tools are approved for what. This is Session 1's tier scheme written for students, and it must agree with the institution's data policy (at Northbridge, the interim policy adopted October 23). The categories that belong here: other people's records of any kind (a classmate's work, a roster, an email with names); credentials, keys, and tokens; real logs, captures, or configurations from any production system, including the college's own; unpublished course materials and exams; the student's own ID number, financial information, and health information; and anything a lab says is synthetic but could be mistaken for real if it left the course. The positive half matters as much: name the approved environment (for Northbridge, the campus AI server), say what it is approved for, and say what the consumer tools may see (public material only).

Two complications a good draft handles. First, the assignment material itself: Module 6 handed students a real campus firewall excerpt, which the Session 1 teams classified as Confidential. The redesign uses a synthetic, per-student log, which is both better pedagogy and a data fix. Second, the tool the course requires: in summer 2026 a plagiarism-detection vendor's license terms would have allowed student submissions to train its AI tools until universities objected [40, 42]. A guardrail that requires a tool is making a data decision on the student's behalf, and the contract, not the vendor's blog, is what governs.

> **Model sentence.** Never enter into any AI tool: another person's work or information, any password or key, any log or capture from a real system, unpublished course materials, or your own ID, financial, or health information. Course data is synthetic and may be used in the Northbridge AI Server only. Consumer AI tools may see only material that is already public.

5. Evidence Retention

Must answer: what process evidence a student keeps, in what form, for how long, and when it can be requested. The published guidance is converging. Stony Brook's flagged-paper process tells students in the syllabus to "keep a time-stamped copy of all their drafts" and expects a revision-history conversation if a concern arises [68]; Cornell's guidance is to keep drafts before, during, and after any AI use and to "save the chats" [69]; Loughborough "strongly recommends" keeping plans, drafts, and version history [64]; and the QAA's 2023 advice goes further, noting that a lack of evidence of how tools were used can itself be an academic misconduct question [57]. The proportionality test from Part 4 applies: required of everyone, kept by the student, reviewed by sample or on concern, and retained only for the term plus the appeal window.

> **Model sentence.** For every graded lab, keep your terminal transcript, timestamped history, dated drafts, and any AI chat exports until final grades are posted and the appeal period ends (30 days). The instructor reviews a random sample each module and may ask for yours if there is a question about your work; a request is a conversation, not an accusation. Evidence is submitted through the course LMS, never by email, and is deleted at the end of the retention period.

Retention periods should match your institution's records schedule for graded work; many colleges keep graded material one term past the grade appeal deadline. Ask the registrar before you print a number.

Guardrails: Accessibility and Academic Integrity

6. Accessibility

Must answer: how approved assistive technology and accommodations relate to the AI rules, who decides, and how a student asks without disclosing a disability to the class. The problem is new and specific: the grammar checkers, read-aloud tools, and summarizers that students receive as accommodations have added generative features. Jisc's national AI centre pointed out in December 2024 that "no AI" assessment levels "lack consideration for AI's role in assistive technology," and that Grammarly, which some students receive through disability funding, is now hard to classify [82]. George Mason's assistive technology office resolved it one way: its Grammarly licenses go only to students with approved accommodations, and "the generative AI features have been disabled for all student accounts" [83]. Goucher College resolved it another: a per-course "Use of Artificial Intelligence Agreement" naming the tool, the use, and the limits, signed by the student, the instructor, and accessibility services [84]. Texas Tech's sample syllabus statements, updated for fall 2026, exempt "basic grammar, spelling, and punctuation features, approved assistive technologies, and approved disability accommodations" from the course's AI restrictions [70].

Three things a draft must do. Route the decision to the accessibility office, not the instructor's judgment of what counts as AI. Give the student a private channel. And check that every evidence requirement in area 5 can be met by a student who uses a screen reader, voice input, or extended time: a `script` transcript can; a requirement to record your screen may not. Part 6 has the Title II deadlines that make this a compliance question as well as a fairness one.

> **Model sentence.** Approved assistive technology and accommodations are never a violation of this course's AI rules, including tools with generative features when they are part of an approved accommodation. If you are unsure whether a tool you use is covered, ask Accessibility Services or email me privately; you do not need to explain why. Every evidence requirement in this course has an accessible alternative; ask for it.

7. Academic Integrity

Must answer: what counts as a violation, how a concern is raised, what evidence the instructor will and will not rely on, the student's opportunity to respond, and the consequences. *Harris v. Adams* shows a plain plagiarism rule covering pasted model output [36]; *Newby v. Adelphi* shows a finding that rested on a detector score being annulled for lack of a fair process [37]. Write the rule so it names the conduct (submitting work you did not do as your own, using AI beyond the stated level, failing to disclose), write the process so it starts with the evidence and a conversation, and write the sentence most syllabi are missing: what the instructor will not rely on.

> **Model sentence.** A violation is submitting as your own work that you did not do, using AI beyond the level stated for the assignment, or failing to disclose AI use. If I have a concern, I will ask you to walk me through your work with your evidence; no finding in this course rests on an AI-detection score, and I do not use detection tools. You will have the chance to respond before any grade or referral. First instance: the assignment is redone at the stated level with a grade cap; second: a zero and referral under Policy 5.12.

PART 6

The Law: FERPA and the Tools You Upload To

Session 1 covered FERPA from the data side: what an education record is, and under what conditions a vendor may see one. This part applies it to the one decision every instructor makes without noticing: pasting a student's work into something.

Student Work Is a Record

Under 34 CFR 99.3, education records are records directly related to a student and maintained by the institution or a party acting for it. A graded submission qualifies; so does an ungraded one once it is in the LMS. Disclosing it to a third party without consent requires an exception, and the one that applies to vendors is the school-official exception in 99.31(a)(1)(i)(B): a contractor may receive records if it performs an institutional service or function for which the institution would otherwise use employees, is under the institution's direct control with respect to the use and maintenance of the records, and is subject to the redisclosure limits in 99.33 [74]. The Department of Education's privacy office spelled out in 2014 what "direct control" means for online services: a contract that limits use to the authorized purpose, bars redisclosure, and gives the institution the ability to control the data [75]. A free website with a click-through agreement is none of those things.

Institutions Have Said So

UT Austin's provost office publishes guidance that begins, "Student work is an educational record protected by FERPA," classifies AI detection software as high-risk, and prohibits its use without a university contract or purchase order; it notes the university has no such contract [30]. USC's registrar, in guidance modified in April 2026, warns that "uploading student information into a generative AI platform may constitute a violation of FERPA" [76]. The University of Utah's grading guidelines require that "if student work will be processed by any AI system for any purpose, it must first be fully deidentified," and permit only contracted tools even then [77]. The Northbridge interim policy says the same thing in its section 4, which is why Lab 4 runs the viva prompt on the campus server with history off, and why Dana Okafor stopped before uploading thirty-four reports to a detector.

What This Means for a Guardrail

Action	FERPA reading
Instructor pastes a submission into a free detector or chatbot	A disclosure with no exception. Do not.
Instructor runs a submission through the campus server (institution-controlled, no third party)	No disclosure; internal processing. Follow the data policy's conditions (history off, named reviewer).
Instructor uses a contracted grading or detection tool	Permitted if the contract meets the school-official conditions; check with the privacy office, and read the training clause.
Student pastes their own work into a consumer tool	Not a FERPA disclosure (the student holds the rights to their own record), but the course's prohibited-data rule still applies to anything else in the paste.
Student is required to use a third-party tool that retains submissions	The institution has chosen a vendor; the contract, not the EULA, governs; the training clause is the one to read (Part 3, "Who Owns the Student's Work").

This part is a description of the regulation and of published institutional guidance, not legal advice. Your privacy officer or counsel decides what your institution's contracts permit.

Accessibility, Assistive Technology, and the Policy Landscape

ADA Title II and the Web Rule

On April 24, 2024 the Department of Justice published a rule under Title II of the Americans with Disabilities Act requiring the web content and mobile apps of state and local government entities to conform to WCAG 2.1 Level AA [78]. Public community colleges and universities are covered; ADA.gov's fact sheet names them [80]. The original compliance dates were April 24, 2026 for entities serving populations of 50,000 or more and April 26, 2027 for smaller entities. An interim final rule published and effective April 20, 2026 extended both by a year: **April 26, 2027** and **April 26, 2028**; the Department said it "fully anticipates implementing the regulation at the new deadline" and may issue further rulemaking on the substantive requirements [79]. The population that determines the date is that of the city or state that runs the institution, by the 2020 Census, not its enrollment [81]. Course content in an LMS, course documents, and the web tools a syllabus requires students to use are in scope.

For a syllabus guardrail this has two consequences. Any tool the course requires (the campus AI server's web interface, an evidence-submission form, a transcript viewer) must be accessible by the deadline. And any evidence or validation requirement must have a path a student using assistive technology can take: a terminal transcript is text and works with a screen reader; a requirement to record a screen or to type under time pressure may not. Note also that the Education Department's Office for Civil Rights resource on avoiding discriminatory AI use (November 2024) has since been marked rescinded, so the Title II rule and the ADA itself are the operative federal authority on accessibility of AI-related requirements.

North Carolina

The North Carolina Community College System has published an AI guidance handbook and faculty guide and runs an AI community of practice through its virtual learning community [85]; the UNC System's 2025 approach is an advisory council and a systemwide skills module rather than a formal policy. Two bills filed in spring 2026 touch instruction: SB 864 addresses K-12 only, and HB 1161, an omnibus AI protections bill in committee as of this writing, would direct the State Board of Community Colleges to require each college to adopt classroom AI standards [86]. No enacted North Carolina law or State Board policy governs AI in community college instruction as of October 2026. If HB 1161 or a successor passes, a department that already has a tested syllabus section will be the one others copy.

Federal

Executive Order 14277 (April 23, 2025) created an AI education task force and a Presidential AI Challenge and made AI a priority in teacher training; it does not address academic integrity or postsecondary assessment [87]. The Department of Education's final grant priority "Advancing Artificial Intelligence in Education" (April 13, 2026) includes using AI to support postsecondary instruction and, again, says nothing about integrity [88]. The practical reading: federal policy is pushing AI into instruction with money and silence on assessment, which leaves the assessment question to departments, which is where Session 2 puts it.

PART 7

Taking It Home

Running Lab 3 With Your Own Faculty or Students

Lab 3 generalizes to any assignment with a rubric and a dataset. Replace Module 6 with one of yours; keep the structure: predict before running, run the lazy prompt and the careful one, validate every claim by command before scoring, score a mix of real and generated submissions on the rubric and on the competency, then write the measures-versus-claims sentence. Two cautions. Generate the "AI submissions" yourself from synthetic data, never from real student work. And run the models on hardware you control; Session 1 explained why, and Part 6 makes it a FERPA question the moment a real submission is involved. With students, Lab 3 is an AIAS Level 5 assignment in its own right: break this assignment and report what the model did and did not do. Students who have watched a model invent an IP address validate their own work differently afterward.

Running Lab 4

Lab 4 works as a department workshop in two hours with the canvas, the guardrails template, and the scenarios from the range. The step most departments skip is testing the guardrails against scenarios; it is also the step that finds the contradictions between the AI rules and the accommodation process, and between the prohibited-data rule and the data the assignments hand out. Bring the department's own data policy, if it has one, and the accessibility office, if it will come. The deliverable that generalizes is the seven-area section with the law noted beside each area; the model sentences in Part 5 are a starting draft, not a finished one.

The Detector-Free Integrity Process

- [ ] Every assignment states its AIAS level and the one-sentence reason, on the assignment.
- [ ] Process evidence is required of everyone, kept by the student, and reviewed by sample, never only from students the instructor suspects.
- [ ] Technical claims are validated by the student as part of the work, and the validation output is graded.
- [ ] A sample of students answers for the work in a short check-in each module; anyone may volunteer; questions come from the student's own submission.
- [ ] A concern is raised from the work and the evidence, in a conversation, with the student able to respond before any grade or referral.
- [ ] No finding rests on a detection score, and the syllabus says so. The record of any finding states what was relied on.
- [ ] No student work leaves institution-controlled systems without a contract that meets the FERPA school-official conditions.
- [ ] Every requirement has an accessible path, and the accessibility office, not the instructor, decides what assistive technology is covered.

What to Say to a Curriculum Committee

Three sentences, each with a source. The assignment we had could be completed by a model in under two minutes and scored 19 of 20 on our own rubric; here is the transcript (Lab 3). Detection cannot repair that, as OpenAI, Vanderbilt, and the courts have found [19, 25, 37]. The redesign measures what the catalog promises, costs under double the grading time, and matches how the certification bodies our students sit for already assess [59, 10].

What Session 3 Does With Today

The invented IP address in Submission A is a retrieval failure: the model answered from the shape of a thousand other incident reports instead of from the log in front of it. Session 3 grounds Northbridge's models in the college's own documentation and current threat intelligence, and the mission tests whether the answers get better or merely more confident. Bring your Evidence Log; the rows you wrote today for the two Lab 3 runs are the baseline.

PART 8

Mapping Today to CompTIA SecAI+

CompTIA's SecAI+ exam (CY0-001) launched February 17, 2026, with four domains: basic AI concepts related to cybersecurity (17 percent), securing AI systems (40 percent), AI-assisted security (24 percent), and AI governance, risk, and compliance (19 percent) [89]. No objective addresses academic misuse. The session still maps, because an assessment policy for a security program is governance of how the program's own people use AI, and the detection record is the risk literature applied to a classroom. Objective numbers are as published in the exam objectives; wording is paraphrased.

Today	SecAI+ objective	Why it maps
Block 1 and Lab 3: the bypass	1.1 AI types and techniques; 3.2 how AI enables or enhances attack vectors (AI-generated content, impersonation)	A student who can prompt a model into a passing report can prompt it into a convincing phishing email. The capability Lab 3 measures is the same one objective 3.2 asks candidates to recognize; the lazy prompt and the CO-STAR prompt are two attacker skill levels.
Block 2: detection	4.2 Risks: hallucination, bias; shadow AI	Detector false positives concentrated on non-native writers are the bias objective in a grading context. A model claiming authorship of text it never saw is hallucination. An instructor uploading records to a free detector is shadow AI.
Demo 4 and Lab 4, Stage 2: the viva generator	2.3 Access controls; 4.1 private versus public models	Drafting check-in questions on the campus server with history off, because the input is an education record, is the private-model decision the courseware teaches, applied to a real case.
Lab 4, Stage 3: guardrails	4.1 Governance: data rules by classification; 4.3 compliance, sanctioned versus unsanctioned use	The prohibited-data guardrail extends the Session 1 tier scheme to student use; the acceptable-use guardrail is a sanctioned-tool policy for a course.
Process evidence and disclosure	2.5 Monitoring and auditing	A transcript, a chat export, and a signed disclosure are an audit trail in a student's hands; the instructor's sample review is the monitoring.
Evidence Log	2.5 Monitoring and auditing; 4.3 documentation	Every model run today is logged with a validation method and a verdict, which is the habit the governance domain describes.

Sessions 3 through 5 pick up 1.3 (the AI life cycle, with retrieval), 2.2 and 2.4 (controls), 2.6 (poisoning, inversion, extraction), 3.1 (AI tools in operations), and 3.3 (automation). For faculty teaching toward the exam, the useful sentence is that the courseware's own prompt exercises run in Open WebUI with a system role, which is the same environment the labs use, so a student who has done Labs 1 through 4 has done the courseware's hands-on work on the way.

REFERENCE

Glossary

Term	Meaning as used in this session
AI Assessment Scale (AIAS)	A five-level, per-assessment declaration of permitted AI use, published by Perkins, Furze, Roe, and MacVaugh (2024) and revised the same year: No AI, AI Planning, AI Collaboration, Full AI, AI Exploration.
Authentic performance	A task whose artifact, audience, and constraint match what a professional would face; the first of the five properties.
Base rate	How common the thing a test looks for is in the population tested. When it is rare, even an accurate test's positives are mostly false.
Curriculum injection	Submitting model output for an assignment that cannot distinguish it from the student's own work. Named by analogy to prompt injection.
Detector	A classifier that estimates whether a text was machine-generated, from its statistical properties. Not a record of what any model produced.
Disclosure statement	The student's signed account of AI use: tools, purpose, extent, and oversight (the Elon and AAC&U elements).
Education record	Under FERPA, a record directly related to a student and maintained by the institution; includes submitted work.
False positive rate	The share of human-written texts a detector flags as AI. Vendor figures are usually document-level and at a chosen threshold; sentence-level rates are higher.
Hybrid submission	Work drafted by a model and corrected or extended by the student; Submission D. The common case, and the one no detector or tell resolves.
Interactive oral	A short, structured conversation in which a student answers for submitted work; "viva" in UK and Australian usage.
Lane (secured, open)	The University of Sydney's two-lane sorting: supervised assessment for assurance, used sparingly; open assessment with tools allowed and documented, for learning.
Legacy assignment	An assignment designed before generative AI whose grade rides on a product a model can produce from the assignment text and data.
Paraphrase attack	Rewriting model output, by hand or with another model, so that detectors and watermarks no longer recognize it.
Process evidence	Artifacts the work leaves behind as it is done: transcripts, timestamped history, drafts, chat exports.
School-official exception	FERPA's provision (34 CFR 99.31(a)(1)(i)(B)) allowing a contractor to receive education records when it performs an institutional function under the institution's direct control.
`script`	The Unix command that records a terminal session to a file with start and end timestamps.
Technical validation	The part of an assignment where the student proves a claim or a fix works, and the proof is graded.
Title II web rule	The 2024 Department of Justice rule requiring public entities' web content to meet WCAG 2.1 AA; compliance dates April 26, 2027 and April 26, 2028 after the 2026 extension.
Watermark	A statistical signal a provider embeds in generated text at sampling time, detectable only with the matching detector; absent from locally run open-weight models.
WCAG 2.1 AA	The Web Content Accessibility Guidelines conformance level the Title II rule adopts.
